Quality of Service Validation

http://www.ixiacom.com/blackbook

December 2011

Your feedback is welcome

Our goal in the preparation of this Black Book was to create high-value, high-quality content. Your feedback is an important ingredient that will help guide our future books.

If you have any comments regarding how we could improve the quality of this book, or suggestions for topics to be included in future Black Books, please contact us at <u>ProductMgmtBooklets@ixiacom.com</u>.

Your feedback is greatly appreciated!

How to Read This Book

The book is structured as several standalone sections that discuss test methodologies by type. Every section starts by introducing the reader to relevant information from a technology and testing perspective.

Each test case has the following organization structure:

| Overview | Provides background information specific to the test case. |
|------------------------------------|--|
| Objective | Describes the goal of the test. |
| Setup | An illustration of the test configuration highlighting the test ports, simulated elements and other details. |
| Step-by-Step Instructions | Detailed configuration procedures using Ixia test equipment and applications. |
| Test Variables | A summary of the key test parameters that affect the test's performance and scale. These can be modified to construct other tests. |
| Results Analysis | Provides the background useful for test result analysis, explaining the metrics and providing examples of expected results. |
| Troubleshooting and Diagnostics | Provides guidance on how to troubleshoot common issues. |
| Conclusions | Summarizes the result of the test. |

Typographic Conventions

In this document, the following conventions are used to indicate items that are selected or typed by you:

- **Bold** items are those that you select or click on. It is also used to indicate text found on the current GUI screen.
- *Italicized* items are those that you type into fields.

QUALITY OF SERVICE VALIDATION

Dear Reader

Ixia's Black Books include a number of IP and wireless test methodologies that will help you become familiar with new technologies and the key testing issues associated with them.

The Black Books can be considered primers on technology and testing. They include test methodologies that can be used to verify device and system functionality and performance. The methodologies are universally applicable to any test equipment. Step by step instructions using Ixia's test platform and applications are used to demonstrate the test methodology.

This tenth edition of the black books includes twenty two volumes covering some key technologies and test methodologies:

| Volume 1 – Higher Speed Ethernet | Volume 12 – IPv6 Transition Technologies |
|---------------------------------------|---|
| Volume 2 – QoS Validation | Volume 13 – Video over IP |
| Volume 3 – Advanced MPLS | Volume 14 – Network Security |
| Volume 4 – LTE Evolved Packet Core | Volume 15 – MPLS-TP |
| Volume 5 – Application Delivery | Volume 16 – Ultra Low Latency (ULL) Testing |
| Volume 6 – Voice over IP | Volume 17 – Impairments |
| Volume 7 – Converged Data Center | Volume 18 – LTE Access |
| Volume 8 – Test Automation | Volume 19 – 802.11ac Wi-Fi Benchmarking |
| Volume 9 – Converged Network Adapters | Volume 20 – SDN/OpenFlow |
| Volume 10 – Carrier Ethernet | Volume 21 – Network Convergence Testing |
| Volume 11 – Ethernet Synchronization | Volume 22 – Testing Contact Centers |

A soft copy of each of the chapters of the books and the associated test configurations are available on Ixia's Black Book website at http://www.ixiacom.com/blackbook. Registration is required to access this section of the Web site.

At Ixia, we know that the networking industry is constantly moving; we aim to be your technology partner through these ebbs and flows. We hope this Black Book series provides valuable insight into the evolution of our industry as it applies to test and measurement. Keep testing hard.

Errol Ginsberg, Acting CEO

Quality of Service Validation

Test Methodologies

This booklet provides baseline test execution plans for running common QoS testing scenarios. It offers a comprehensive set of recommendations and guidelines for running test cases against various QoS policy implementations.

Quality of Service (QoS) Validation

Quality of service (QoS) is a network's ability to prioritize end-to-end traffic delivery based on traffic type, specific user, or service type, over various underlying technologies such as:

- Frame relay
- ATM
- Ethernet and 802.1
- SONET
- IP-routed networks

The increasing volumes and types of traffic flowing through today's networks require prioritization. Network managers use QoS to maintain high network performance for delivering time-sensitive traffic – such as high-quality video and real-time voice -- during periods of network congestion. QoS assists in traffic prioritization by managing the delay, delay variation (jitter), bandwidth, and packet loss parameters on a network, and provides improved traffic delivery and more predictable network service.

QoS can be implemented at layer 2 and/or layer 3. QoS methods are varied and include such techniques as VLAN priority (802.1p), IP Precedence (TOS), and differentiated services code points (DSCP).

Some typical methods for implementing QoS are:

- Classification typically the function of edge routers that organize traffic into classes based on specified criteria.
- Congestion management operates to control congestion once it occurs. One method
 for handling traffic is using a queuing algorithm to sort the traffic and determine priority to
 the output link. Each queuing algorithm solves a specific network traffic problem and
 affects network performance in a specific way.
- Congestion avoidance monitors network traffic loads to anticipate and avoid congestion at common network bottlenecks before they become a problem. These techniques are designed to provide preferential treatment for premium (priority) class traffic under congestion situations. Congestion avoidance concurrently maximizes network throughput and capacity while minimizing packet loss and delay.
- Policing and shaping regulates network traffic based on committed access rate (CAR) and peak rate. Once a service exceeds its SLA, out-of-profile traffic is marked down or dropped. Shaping regulates network traffic by delaying excess traffic, smoothing bursts, and preventing unnecessary drops.

 Signaling – provides a way for an end station or network node to request special handling of specified traffic from its neighbors. QoS signaling can coordinate the traffichandling techniques provided by other QoS features. It plays a key role in configuring successful overall end-to-end QoS service across a network.

QoS provides the preferential delivery of application traffic by ensuring sufficient bandwidth, controlling latency and jitter, and reducing data loss. The following table describes QoS network characteristics.

| Network Characteristic | Description |
|------------------------|--|
| Bandwidth | The rate at which traffic is carried by the network. |
| Latency | The delay in data transmission from source to destination. |
| Jitter | The variation in latency. |
| Reliability | The percentage of packets discarded by a router. |

Table 1. Network Characteristics managed by QoS

The Internet Engineering Task Force (IETF) defines two major models for QoS on IP-based networks: integrated services (Intserv) and differentiated services (Diffserv). Each model includes mechanisms that provide preferential treatment to specified traffic. Table 2 lists the two general categories of QoS mechanisms.

QUALITY OF SERVICE VALIDATION

Table 2. QoS mechanisms on IP-based networks

| Category of QoS mechanism | Description |
|------------------------------|--|
| Admission Control | Determines which applications and users are entitled to network resources, by specifying how, when, and by whom network resources on a network segment (subnet) can be used. |
| Traffic Control | Shapes traffic using rate-of-flow limits, and regulates data flows by classifying, scheduling, and marking packets based on priority. Traffic control mechanisms police delivery to the network by segregating traffic into service classes. The assigned traffic flow service class determines the received QoS treatment. |

The Intserv model uses both resource reservation and traffic control mechanisms to enact special handling of individual traffic flows. The Diffserv model uses traffic control to enact special handling of aggregated traffic flows.

QoS Benefits

The two most common approaches used to satisfy the service requirements of applications are:

- Over provisioning
- Managing and controlling

Over provisioning allows for allocating resources to meet or exceed peak load requirements. Over provisioning is only effective if it requires upgrading to faster local area network (LAN) switches, faster network interface cards (NICs), adding memory, adding CPU, or adding disk space. Over provisioning is not viable when dealing with expensive long-haul wide area network (WAN) links, under-used resources, or congestion during short peak periods.

A managing and controlling strategy focuses on allocating network and computing resources. Resource management tries to optimize resource usage by limiting bandwidth, CPU cycles, and network switch buffer memory.

Load management and network design versus implementing QoS is a common debate. In reality, QoS policies are often needed even in a well-designed and well-provisioned network. QoS policies can:

 Delay or reduce the need for expansion and upgrades by using existing resources efficiently

- Prevent bandwidth needs from growing faster than the resources of any good network designer
- Allow administrators to manage the network from a business perspective (rather than an technical one) by giving them control over network resources
- Ensure that time-sensitive and mission-critical applications have the resources they require
- Give service providers an added revenue stream by allowing different Service Level Agreements (SLAs) to be sold at different rates (gold, silver, or bronze) based on QoS classifications
- Improve user experience.

There are many ways to implement QoS. Different domains, which may or may not use different technologies and resources, can employ separate QoS implementations to monitor specific portions of the end-to-end path. Two particular domains of implementation are:

- Enterprises. Enterprises can control their own networks and systems using IEEE 801.p to mark frames according to priorities. 801.p marking allows the switch to offer preferential treatment to certain flows across virtual local area networks (VLANS). Process computing can obtain differentiated services by using QoS services to mark specific traffic to run at higher priorities.
- Network Service Provider (NSP). NSPs aggregate and forward traffic within their network, or hand it off to another NSP. The NSP use technologies such as DiffServ or IntServ to prioritize the traffic handling. NSPs must use QoS policies to enforce SLAs for transit traffic.

QoS Test Challenges

Network convergence

Quality of service (QoS) and maximum throughput are essential for delivering data, voice, and video on Ethernet networks, but traditional testing methods often fall short in their ability to monitor, analyze, and identify critical problems. VLAN, MPLS, and IP service turn-ups require a multi-stream, multi-port, and multi-service testing model. Such testing helps the provider keep service quality and revenues up.

Proper network pre-qualification and monitoring is imperative to ensure that service quality is maintained throughout the network. The commercial services offered range from LAN extension, Internet access, voice, video, and data storage. Since these services all reside on the same network and consume a portion of the shared bandwidth, they must be qualified at the same time. These types of traffic have very different requirements, and stress the network in a unique manner.

In a converged network, service availability is absolutely critical. As mission-critical applications are converged onto a single infrastructure, network fault-tolerance and resiliency become increasingly important. Since a one-minute network outage affecting 100 customers could cost a service provider several hundred thousand dollars, it's obviously why their top concerns are network reliability and availability. In short, high-availability converged networks are a prerequisite for service providers interested in offering reliable and profitable carrier-class services. A QoS provisioned, well-designed network facilitates a highly available network that reduces the CAPEX and OPEX associated with redundant network infrastructures.

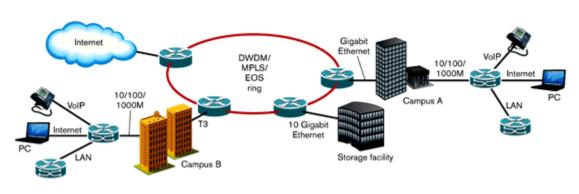

Ethernet Everywhere

Ethernet services have typically run point-to-point -- from one business campus to another or from one data center to another. These early Ethernet services were straightforward to turn-up, monitor and maintain. Testing was isolated to a single dark fiber, a single wavelength on a DWDM network, or a single channel in an Ethernet over SONET/SDH network. Performance was verified by completing hard loopback tests running at data rates of 10 Mbps, 100 Mbps, or 1 Gbps, based on the bandwidth sold.

Performance verification of Ethernet services was a simple task under those circumstances. Many services were sold as a fixed bandwidth without any QoS designation -- a promise of nonguaranteed bandwidth was sufficient.

Service providers did not provide traffic grooming or policing to ensure the QoS -- they simply installed the network, verified end-to-end throughput, made a note of the roundtrip delay, and performed troubleshooting when customers complained. Now, however, network providers must conform to standards established by the ITU and Metro Ethernet Forum (MEF) as the demand for Ethernet services and bandwidth continues to increase. This means adding more capacity without impacting existing services.

Today's providers must offer the option of multiple services tiers based on QoS levels when selling commercial Ethernet services. Today, providers have significantly more flexibility in offering Ethernet services by grooming networks to handle differentiated services. In addition, Ethernet-over-copper solutions provide much greater bandwidth control and cost savings when using existing T1 and T3 infrastructures.

Complexity

Traditional test sets focused on stressing one piece of the puzzle at a time, by testing each service type separately. Such tests no longer provide adequate coverage for networks that provide triple play services and multiple types of traffic simultaneously. Differentiated services existing side-by-side on the network must be tested simultaneously.

To verify differentiated services, tests must generate traffic streams in the same format (VLAN, MPLS, IP) used by the network architecture for each service type. Testing the priority and/or TOS for each traffic stream must be specified based on the appropriate class of service.

At the far end, tests must separate and perform QoS measurements on each traffic stream (see Figure 1). Though each service may individually meet QoS standards, multiple services can negatively impact performance by increasing the traffic load. Services must be tested at higher than the maximum subscribed rate to verify network's ability to handle future policing and load management.

A network device must be tested on all ports, not just a single port, to confirm its effectiveness in the network. Network deployments must be overstressed to determine their potential – the ability of a network to handle future QoS provisioned traffic is just as important as its current level of efficacy.

Introduction to L2 QoS

L2QoS provides best-effort quality of service (QoS) or class of service (CoS) at layer 2 without requiring reservation setup. User priority as defined by the 802.1p specification (also called class of service) is used to prioritize network traffic at the data link/MAC sub-layer.

The 802.1p field is a three bits field in the 802.1Q header of an Ethernet tagged frame. It defines eight different classes of service using a priority value between 0 and 7 (inclusive). It identifies the class of the incoming traffic and transmits it based on class when the switch or network is congested. Figure 1 shows the format of a VLAN header.

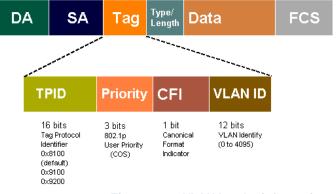

Figure 92. VLAN header information

Network administrators can setup the queues to match various business requirements and priority levels. The IEEE recommendation for QoS classifications is shown in Table 3.

| User Priority | Traffic Type |
|---------------|-------------------------------------|
| 1 | Background |
| 2 | Spare |
| 0 | Best Effort |
| 3 | Excellent Effort |
| 4 | Controlled Load |
| 5 | "Video" < 100 ms latency and jitter |
| 6 | "Voice" < 10 ms latency and jitter |
| 7 | Network Control |

Table 3. IEEE classifications

L2QoS is an important component when implementing end-to-end QoS across service provider or enterprise networks. Implementing combined QoS functionality at multiple network locations guarantees that end-to-end service level agreements (SLA) can transmit real-time or missioncritical application traffic (such as video and voice traffic) as desired.

Test Case: Layer 2 Quality of Service

Overview

Ethernet services such as commercial triple play and mobile backhaul must comply with strict SLAs. As end-users increase their demands for high quality of experience (QoE), meeting agreements to deliver mixed data, voice, and video traffic over an IP network is increasingly important. New and complex QoS features have grown significantly, requiring more comprehensive test methodologies.

Router and switch venders must validate that their devices can handle QoS features such as classification, queue scheduling, and buffer management under different traffic loads. They must confirm that the various queuing mechanisms such as a weighted round robin (WRR) and weighted early random detect (WRED) are implemented correctly so as to prevent high priority traffic being dropped. Enterprise network administrators need to validate QoS settings to verify bandwidth for mission critical applications. Service providers need to validate network design and configuration to provide and monitor customer SLAs.

L2QoS is typically implemented in access and metro Ethernet networks where packets are switched instead of routed. It enables bridges/switches to reduce processing time by inspecting layer 2 headers for QoS information, without looking at layer 3 content.

The following key measurements need to be collected in order to test a device's L2 QoS implementation:

- Throughput
- Frame loss
- Latency
- Jitter

These metrics are inspected for each traffic class at various traffic loads and frame sizes in order to validate the DUT or network's conformity to configured QoS policy.

Objective

Most of the routing/switching vendors implement a complex queuing and scheduling mechanism to process packets with different priorities. Different VLAN priorities are mapped to different queues. The objective of this test is to verify the scheduling function of the DUT's output queue. In the test, IxNetwork's advanced traffic wizard builds traffic with various CoS values, and defines flow tracking per CoS value. Congestion is created at the DUT output port, and

IxNetwork aggregated and multi-level drill-down statistics are used to monitor frame loss, latency and, jitter at each CoS level.

By monitoring frame loss, latency, and jitter at each CoS level, the scheduling function of the DUT's output queue can be validated against various QoS configurations.

Setup

In this test, three Ixia ports are connected to the Gigabit Ethernet interfaces of a DUT switch. The DUT interfaces are configured as trunk ports.

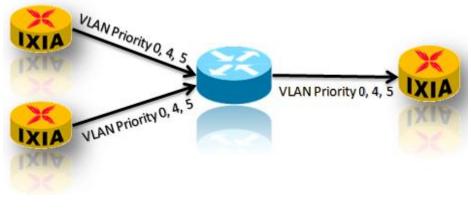

Figure 93. L2QoS test topology

There is one priority queue and two WRR queues on the line card of the DUT interfaces. The values for CoS value-to-queue mapping and bandwidth allocation between queues are listed below.

| Queue | Bandwidth | VLAN Priority |
|--------------------|-----------|---------------|
| 1 - WRR low | 30% | 0, 1, 2, 3 |
| 2 - WRR high | 70% | 4, 6, 7 |
| 3 – Priority queue | | 5 |

Table 4. DUT output queue configuration

Layer 2 traffic is sent from two Tx ports to one Rx port. The traffic is configured with three VLAN priority values (0, 4, and 5) and three frame sizes (512, 1280 and 68) to emulate data, video, and voice traffic. To monitor frame loss, latency, and jitter for each VLAN priority, traffic tracking is configured by VLAN priority (three flows for the different VLAN priority values). Initially, traffic is sent at a low rate so that the Rx port is not oversubscribed and all frames are received. Then the traffic rate is increased to create oversubscription at the Rx port. The DUT congestion management feature will kick in and drop low priority traffic.

Step by Step Instructions

- 1. Configure the DUT interfaces connected to the three Ixia ports as trunk ports, to pass traffic for VLAN 121 to VLAN 130. Enable QoS features at a global level.
- 2. After reserving ports, go to the **Protocol Configuration > Static** window. Click **LANs** tab, and then click **Add** LANs . The **Add Static Lans** dialog box appears.

| Add Static Lans |
|---|
| Add # Static Lans per Port |
| Select the Ports to include |
| 10.200.134.41:02:04-Ethernet 10/100/1000 Base T |
| ✓ 10.200.134.41:02:05-Ethernet 10/100/1000 Base T |
| ✓ 10.200.134.41:02:06-Ethernet 10/100/1000 Base T |
| |
| Select All Clear All |
| OK Cancel |

Figure 94. Configure static MAC ranges

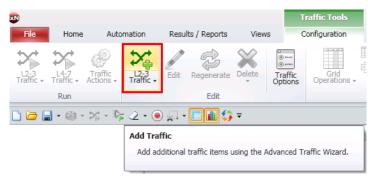

- 3. Click **Select All** in the **Add Static Lans** dialog box to select all three ports, and then add one static LAN per port.
- 4. Click **OK** to close the **Add Static Lans** dialog box.
- 5. In the LANs tab add the MAC Address and Count Per LAN Range.

| Diagram IP LANS FR ATM Interface Groups Interfaces In Groups | | | | | | | | |
|--|--------------------|----------|-------------------|------------------|-------|----------------|---------------|---------|
| ++ 🗙 🏹 🕅 Static | | | | | | | | |
| | Port | Enable | MAC Address | Increment MAC | Count | Enable VLAN | VLAN Count | VLAN ID |
| 1 | 10.200.134.41:02:0 | V | 00 00 00 01 00 01 | ☑ | 100 | | 1 | 1 |
| 2 | 10.200.134.41:02:0 | | 00 00 00 02 00 01 | ☑ | 100 | | 1 | 1 |
| 3 | 10.200.134.41:02:0 | | 00 00 00 03 00 01 | | 100 | Γ | 1 | 1 |

Figure 95. Customized static MAC ranges

6. Go to **Traffic Configuration** and click **Advanced Traffic Wizard** to start the advanced traffic wizard.

TEST CASE: LAYER 2 QUALITY OF SERVICE

- In the Endpoint selection window, select Ethernet/VLAN as the Type of Traffic. Then select the MAC range on port 1 and 2 in the Source window and select MAC range on port 3 in the Destination window.
- 8. Click the Add button 🕑 to add selected endpoints.

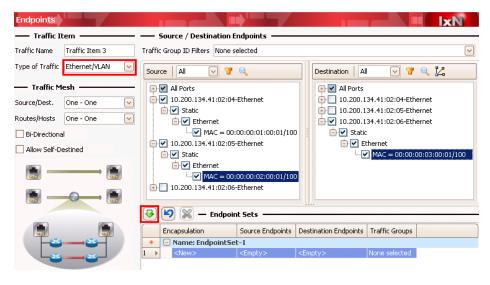

Figure 97. Advanced traffic wizard - endpoint

- Click Next to go the Packet/QoS window., Optionally, click the Packet/QoS tab in the left panel. The Packet/QoS window presents the packet view and QoS grid. The available QoS fields are populated dynamically based on packet content.
- 10. In the **Packet/QoS** page click the **VLAN** button stored to append the VLAN header. Then, Highlight the VLAN header and click the **Expand** button is to expand the VLAN header. From the VLAN-ID option list, select the value to configure VLAN 121 through 130 with an increment pattern.

The 10 VLAN IDs is distributed across the 100 MAC addressed per Tx port. VLAN ID 121 is used with Mac1, Mac11, Mac21, and so on. VLAN ID 122 is used with Mac2, Mac12, Mac22, and so on.

| Name | Value |
|--|--|

Figure 98. Advanced traffic wizard - Packet/QoS (Packet Editor)

Click the VLAN priority option list to configure a list pattern with the values of 0, 4, and
 Click Fully Meshed button to fully mesh the QoS values with the existing number of MAC Addresses.

This creates 100 flows, each with three QoS values, for a total of 300 unique flows per Tx Port.

| Name | Value |
|--|--|
| | length: 128 [List] 0 |
| Field Info: Tracked & Fully meshed Field Info: Trac | List 0 Value Single value Increment Decrement List Value 1 0 2 4 3 5 4 <1ype to add value> |

Figure 99. Advanced traffic wizard - Packet/QoS (Packet Editor)

12. In the **Flow Group Setup** window, select **VLAN Priority**. This will group together all flows with the same VLAN priority so that you can configure a different traffic profile for flow groups with different VLAN priority. Three flow groups are created in this test.

| —— Create Flow Groups based on —— | | | | |
|---------------------------------------|--|--|--|--|
| None (use default distribution) | | | | |
| Src/Dest Endpoint Pair | | | | |
| Rx Port | | | | |
| Ethernet II : Destination MAC Address | | | | |
| Ethernet II : Source MAC Address | | | | |
| Ethernet II : Ethernet-Type | | | | |
| Ethernet II : PFC Queue | | | | |
| VLAN : VLAN Priority | | | | |
| VLAN : VLAN-ID | | | | |

13. In the Frame Setup window, leave all parameters at their default value.

14. In the **Rate Setup** window, configure the frame rate to be 5 percent of line rate. For rate distribution, select **Apply port rate to all Flow Groups**. Each VLAN priority flow group will get a 5 percent line rate.

| Line rate 5.00 % Packet rate 100000.00 per second Layer2 Bit Rate 1000.00 bps Flow Groups Apply | — Rate ——— | | |
|---|-------------------|-----------|-----------|
| ○ Packet rate 100000.00 per second ○ Split ○ Layer2 Bit Rate 1000.00 bps ✓ Flow Group | Line rate | 5.00 | % |
| O Layer2 Bit Rate 1000.00 bps V Flow Grou | O Packet rate | 100000.00 | per secor |
| | - | | - |
| | U Layer2 Bit Rate | 1000,00 | loba C |

Figure 101. Advanced traffic wizard – rate setup

15. In the **Flow Tracking** page, select **VLAN Priority** and **VLAN-ID** as tracking options. The traffic item option is automatically selected as long as there is one other tracking option selected.

Note: By Tracking only on VLAN ID and VLAN Priority, IxNetwork only tracks a total of 30 flows in the test, even though there are 300 unique packets created per Tx Port. This is because there are only 10 VLAN IDs multiplied by three VLAN Priorities.

To track all 600 flows across both Tx Ports, select either **EthernetII:Destination MAC Address**, **EthernetII:Destination MAC Address**, or **Source/Dest Value Pair**.

| Flow Tracking | | | | | | | |
|---------------------------------------|--|--|--|--|--|--|--|
| Track Flows by | | | | | | | |
| ☑ Traffic Item | | | | | | | |
| Source/Dest Endpoint Pair | | | | | | | |

Figure 104. Advanced traffic wizard – preview

18. In the **Validate** window, validate the traffic item before actually generating it. The validation process confirms configuration, packets, flow groups, and flows for either the

current traffic item or all traffic items. If there is any problem, it will display an error/warning message and correction suggestions.

| Traffic I | item | Configuration | Packets | Flow Groups | Flows |
|-----------|------|---------------|---------|-------------|-------------|
| L2QoS | | V | V | 6 | V 30 |
| | | | | | |

19. Click **Finish**. A traffic item is created under the **L2-3 Traffic Items** tab in the left panel. Also click **L2-3 Flow groups** to make them appear in the right panel.

Optionally, customize **Frame Size**, **Frame Rate**, **Flow group name**, and so on , for each flow group using the grid operation as well as control the start, stop, suspend, or resume traffic at per flow group level.

Figure 111. Traffic item statistics

25. Select the **Drill Down** icon in the top toolbar, and select **Drill Down per VLAN:VLAN Priority** option. This will drill down within this Traffic Item and display the aggregate statistics for each ingress VLAN Priority.

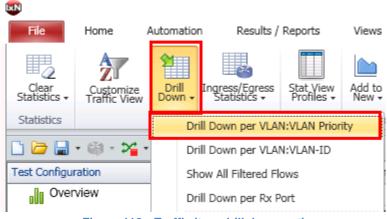

Figure 112. Traffic item drill down options

The traffic rate is 15 percent per Tx port. The Rx port receives about 30 percent of the line rate traffic. There is no congestion and therefore no frame loss at each VLAN priority level. Verify latency and delay variation (jitter). VLAN priority flow statistics provide all the necessary information, as shown below.

Figure 113. VLAN priority flow statistics

26. Highlight the main header row for the flow groups for VLAN priority 0 (simulate data traffic) and 4 (simulate video traffic). Slide the rate bar to about 46 percent of line rate. This generates about 46 percent simulated data and video traffic per Tx port. With the 5 percent voice traffic per port, this creates congestion at the Rx port.

Figure 115. VLAN priority flow statistics

 Select any cell within the stat view from the previous Step. Click the Ingress/Egress Statistics icon on the top toolbar, and then select Ethernet: Outer VLAN Priority (3 bits) at offset 112.

This clearly shows both the Ingress and Egress traffic statistics for this Traffic Item based upon the TOS values going in and coming out of the DUT. This view is useful for QOS Remarking tests.

This view shows sent traffic with VLAN priority 0, 4, and 5, while receiving traffic with VLAN priority 0 for all flows. This explains the statistics in step 22 with high frame loss for high priority traffic. The VLAN priority for all packets is marked at the DUT, given the same priority, and placed in same queue. Smaller voice packets are dropped the most.

Figure 116. VLAN priority flow statistics ingress/egress view

- 29. Configure all three DUT interfaces to view the COS value of incoming packets, and schedule the packets based on the original priority at the congestion point.
- 30. Restart the traffic with the same traffic load as in step 21. The flow with VLAN priority 0 now starts dropping frames, while the other two flows do not (there may be a small frame delta on these two flows, but this is due to packets on-wire and not real frame loss).

L2QoS functionality continues working on the DUT, and incoming packets are differentiated based on their VLAN priority. High priority traffic is given more bandwidth during congestion.

Compare the latency and delay variation (jitter) with normal conditions – both latency and jitter have increased. However, the high priority flow has increased less while the low priority flow has increased more.

Convert the statistics view above to ingress/egress view by right-clicking the view. This view shows that the received packets of a specific flow have the same VLAN priority the value with which they were sent.

Figure 117. VLAN priority flow statistics ingress/egress view

31. Continue increasing the rate to about 49 percent for the flow groups with VLAN priorities 0 and 4 (25 percent and 24 percent respectively). Including the 5 percent traffic for VLAN priority 5, each Tx port sends about 54 percent of the line rate. This increases the congestion at the DUT. Now packets from the flow with VLAN priority 4 start getting dropped. Compare the latency and delay variation (jitter) with previous congestion conditions. Both latency and jitter increased with the congestion increase, but the high priority flow always has the least latency and jitter.

Figure 30. VLAN ID flow statistics

Result Analysis

Without QoS, the CoS value of incoming packets is marked to 0 at the DUT and all flows are treated equally. When congestion occurs, all flows suffer a similar percentage of packet loss, latency, and jitter.

With QoS, flows with different CoS values are treated differently at the DUT. When congestion occurs, flows with higher priority are given more bandwidth and are served at a higher frequency, and suffer less latency and jitter. This can be verified with frame loss and latency/jitter values measured using per-CoS flow statistics.

Troubleshooting and Diagnostics

| Issue | Troubleshooting Tip | | | | | |
|---|--|--|--|--|--|--|
| All CoS flows suffer similar frame loss | Check the DUT's configuration to make sure QoS is enabled at global level, and CoS values are trusted on the incoming port. Alternatively, use Ixia's ingress/egress view to find out receiving packet's QoS value | | | | | |
| DUT does not pass any traffic | Verify that the VLANs used in Ixia traffic are created at DUT and the ports are in forwarding state for the spanning tree instance they belong to. | | | | | |

TEST CASE: LAYER 2 QUALITY OF SERVICE

Test Variables

| Test Variables | Description |
|------------------------------|--|
| # of test ports | Increase # of Tx and Rx ports to validate DUT's capability to perform QoS function concurrently across multiple ports and line cards. |
| # of Mac address | Increase # of source and destination MAC addresses to validate DUT's capability to perform QoS function on a large # of MAC addresses. |
| VLAN ID | Increase # of VLAN IDs to validate DUT's capability to perform QoS function for multiple broadcast domains. |
| Frame Rate | Test DUT's capability to perform QoS function under various traffic loads. |
| Frame Size | Test DUT's capability to perform QoS function under various frame sizes. |
| Integrated Test | Use Integrated Test to find out throughput/latency, frame loss, etc. for traffic with various CoS levels. |
| Event Scheduler program | Create an event scheduler program to iterate frame rates and frame sizes, and snapshot the per-CoS flow statistics view for post analysis. |
| Change encapsulation | Add layer 3 and/or layer 4 encapsulations to the packet and validate QoS function. |
| MPLS Exp bits | Perform similar test for MPLS label-switched traffic by setting various MPLS Exp bits. MPLS is a layer between layer 2 and layer 3. |
| DUT queue bandwidth ratio | Perform similar test with a different queue bandwidth ratio. |
| DUT queue buffer allocation | Perform similar test with a different buffer allocation. |

Conclusions

This test proves that a DUT properly implemented the mapping of packets with different CoS values to different queues, and properly implemented transmit scheduling among different queues.

This test also shows that IxNetwork's advanced traffic wizard can build highly flexible QoS traffic. The aggregated statistics view provides many important benchmarks, such as frame loss, Rx rate (bytes, bits, Mbps, etc), latency, jitter, and sequence error at the traffic-item level, as well as various user-defined levels. The multi-field drill down view helps identify issues quickly by only looking at interesting flows out of large numbers of flow statistics. The egress tracking can track any field of receiving packets. With combined ingress/egress view, real-time statistics are used to identify DUT QoS marking.

IxNetwork's numerous capabilities make QoS testing very easy.

Test Case: Layer 3 Quality of Service

Layer 3 quality of service (QoS) classifies traffic at layer 3 to differentiate between different traffic types. Layer 3 QoS enables the network to improve delivery-sensitive application services and results in predictable network behavior.

Layer 3 QoS Benefits

Layer 3 QoS implementations often improve network functionality, resulting in:

- **True end-to-end QoS layer 3** -- QoS allows network administrators to configure QoS from source to destination endpoints.
- **Optimum efficiency** -- A properly configured layer 3 QoS system creates better network resource management for the various application traffic requirements.
- Assured scalability and performance -- Correctly planned networks ones that include QoS provisioning -- allow for performance improvements that don't require a design overhaul.
- **Customized services** -- Fine tuning QoS policies allows service providers to provide customized services, such as low latency Citrix traffic.

Layer 3 QoS Challenges

Layer 3 QoS must provide customers with the expected service quality and reliability for their latency- and bandwidth-sensitive applications.

Correct queue size configuration

Different types of traffic must be handled differently to achieve optimal network performance. In order to ensure differentiated handling of traffic classes, network switches must support enough queues to accommodate the various traffic classes.

Predictable network performance requires that different traffic types have different queue specifications. Latency-sensitive applications such as video and voice must have priority queuing, while general data applications only need some form of round-robin queuing.

Consistent Policy Across Devices

Traffic path devices must adhere to the same configured QoS policy. Predictable network performance results from classifying packets as close to their source as possible, and enforcing the classification along the entire network path.

TEST CASE: LAYER 3 QUALITY OF SERVICE

Packet Loss

Packet loss is one of the most common factors affecting application traffic. For example, even though voice CODECs can accept some packet loss without dramatically degrading speech quality, the loss of many consecutive packets dramatically affects the end result even if the total loss percentage is low. Even in data transfer traffic scenarios, excessive packet loss causes unnecessary network resource allocation from data retransmissions.

Since voice and data use the same resources in converged networks, voice traffic must have priority treatment over data traffic, which is less affected by delay, jitter, and packet loss.

Effect of Delay on Traffic

It is well known that network delay leads to two-way traffic difficulties. For example, Alice and Bob enact a VoIP call using an IP network with a high round-trip delay (for example, 500 ms). If Alice interrupts Bob, he will continue to speak until the interruption is perceived. It takes a moment to sort out the conversation. To meet quality requirements the one-way delay must be kept below 150 ms.

VoIP calls are just one example of the importance of limiting delay in time-sensitive applications.

Jitter

Jitter is the measurement of receiver delay. Many devices implement a jitter buffer that accounts for the jitter effect. A jitter buffer minimizes delay variations by temporarily storing packets and discarding packets that arrive too late. If a jitter buffer is too small, then an excessive number of packets may be discarded, which can lead to degradation of service.

The most common causes of jitter are network congestion and router/switch queuing methods.

Layer 3 QoS Mechanisms

There are multiple layer 3 QoS mechanisms to satisfy network needs. However, IntServ and DiffServ are the most common methods of implementing layer 3 QoS.

Intserv

IntServ is a rich and granular QoS solution by using RSVP for end-to-end signaling, state maintenance, and admission control. IntServ requires that network elements keep track of each individual traffic flow on the network. This requires that core network routers and switches maintain a soft state by setting aside resources.

Diffserv

Diffserv, while coarser, offers a simpler QoS method by categorizing traffic into different classes and then providing each class a different QoS service. This method sidesteps the issues of cost, complexity, and scalability associated with Intserv.

Diffserv uses the type of service (TOS) byte in IP (both IPv4 and IPv6) headers. There are two Diffserv implementations developed by vendors in the field:

A. TOS/IP Precedence

The TOS byte in the IP header is sub-divided into three different fields. Bits 0-2 give the packet one of the eight possible IP precedence values. Higher precedence packets are dropped less than those with lower precedence. In addition, the TOS field provides different delay, throughput, and reliability to the packet.

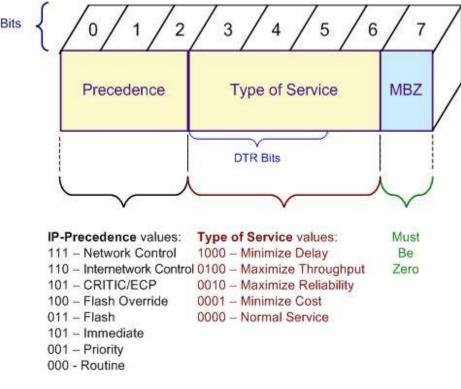

Figure 31. Precedence values in the packet header

The TOS/IP precedence method not only defines the relative priority of a packet, but also assigns ano-drop precedence to packets belonging to the same class. For example, FTP and Telnet traffic may belong to the same precedence class. During network congestion, however, a network operator might assign higher drop probability to FTP traffic.

Three bits in the header for precedence only allows eight possible priority classes.

B. Differentiated Services

Differentiated services have two main components: packet marking and per-hop behavior (PHB).

Packet Marking: The TOS byte in the IP header has been completely redefined. The first 6 bits are set aside for differentiated services code point (DSCP) values. DSCP values are used to support up to 64 different aggregates/classes of traffic.

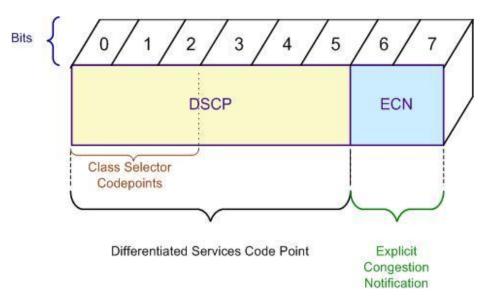

Figure 32. DSCP values

All packets sharing the same DSCP value and direction are called a behavior aggregate (BA).

Per Hop Behavior (PHB): PHB is the packet scheduling, queuing, policing, and shaping performed by a network node on packets belonging to any particular BA. The network operator can configure different policies for different BAs.

The following PHBs are widely used to implement a Diffserv-enabled network:

- Default PHB the PHB defined for packets marked with DSCP value of 000000. Packets marked with this DSCP value get the best effort service.
- Class-Selector PHB the PHB used to ensure compatibility with TOS/IP precedence and is associated with packets marked with DSCP values of the form "xxx000," where xxx correspond to IP-Precedence values.
- Expedited Forwarding PHB the PHB for applications with low-loss, low-latency, low-jitter, and guaranteed bandwidth service, such as VoIP and IPTV.
- Assured Forwarding PHB the PHB that defines which BAs can be assigned priority as well as drop precedence values. This allows for more granular QoS control of packets that share the same class but have different drop precedence (low, medium, and high).

Objective

The objective of this test is to show the DUT QoS performance under different load conditions.

Ixia ports will send traffic with three different TOS values, and the DUT will give different priority to the traffic based on the TOS Precedence field value. Traffic is initially sent below the link threshold on the DUT egress port, and then is increased to cross the DUT egress port link

bandwidth threshold. The DUT is configured to mark the TOS precedence when the bandwidth goes over the configured threshold.

This test demonstrates IxNetwork's QoS test capabilities. The methodology includes automation of DUT configuration via CLI as well as sequencing of IxNetwork traffic events using Test Composer.

Setup

Two Ixia ports are used in this example. Traffic is sent from Ixia Port 1 towards Ixia Port 2 with three QoS values configured. Ixia Port 1 is running at 1000M, and Ixia Port 2 is running at 100M Full Duplex. The DUT processes the packets based upon the TOS precedence values in the IPv4 headers.

The DUT should prioritize TOS values 7, 4 and 0 (in that order).

Step by Step Instructions

The following step-by-step instructions highlight how to set the essential IxNetwork parameters, and explain additional options that can modify the test behavior.

1. Open the IxNetwork GUI, and add two physical ports to the configuration.

Table 5.

2. Under **Protocol Interfaces**, configure two connected protocol interfaces with the following parameters:

Summary of protocol interface parameters

 After configuring the TOS values, create the flow groups. In the Flow Group Setup step, configure flow groups for each TOS precedence value. Select the IPv4: Precedence option.

Note: See the description and diagram on the right explaining how IxNetwork creates Flow Groups based on the type of Flow Grouping selected.

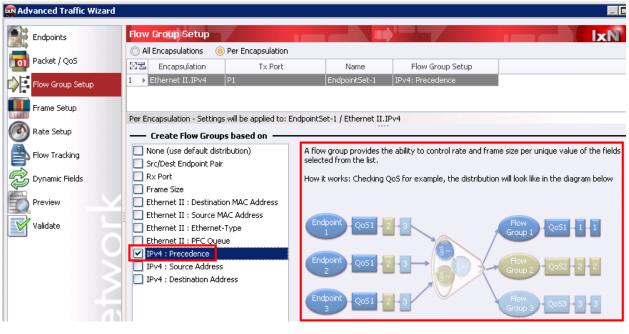

Figure 38. Flow Grouping based on IPv4 precedence

6. In the **Frame Setup**, configure a fixed frame size of 512.

Note. This dialog also allows you to configure frame parameters such as **Frame Size**, **Payload**, **CRC Settings**, and **Preamble Size**.

7. In the **Rate Setup**, configure a line rate of 3 percent.

Note. This dialog allows you to configure the **Transmission Modes** for traffic items and flow groups

8. In **Flow Tracking**, set the **Track Flows by** value to **IPv4: Precedence**. In addition, also configure **Egress Tracking** for the IPv4 TOS precedence field.

Note: This will track the IP Precedence (TOS) field from the DUT ingress and egress side. In some cases the DUT will change the TOS value as traffic flows through the DUT. This usually occurs when the DUT is configured to prioritize certain TOS values over others, and/or to ensure higher priority traffic gets through with low latency and high throughput. This is especially useful in test cases like this which are oversubscribing the DUT Egress port.

Figure 45. Frame rate column

Verify the DUT's behavior by checking the traffic statistics again.
 Note: The DUT prioritizes the high priority TOS value of 7 while discarding the lower priority traffic in this oversubscription environment.

| k - | Back 🔻 👧 🕹 | raffic Item IPv4 :Prece | dence Ethern | iet:IPv4 TOS Pi | recedence (3 bi | ts) at offset 12 |

Results Analysis

The following questions provide guidelines on how to recognize specific problems during or after test execution:

1. Has the test objective been achieved? Check the **IP Precedence** values in the **User Defined Statistics**.

| Table 6. | TOS | Precedence | statistics |
|----------|-----|------------|------------|
|----------|-----|------------|------------|

| Statistic Name | Value | Questions |
|---|-------|--|
| IPv4: Precedence | | Are the ingress and egress IPv4 precedence values the same? |
| Egress Tracking: IPv4 TOS Precedence | | Is the DUT correctly remarking TOS precedence values under different traffic conditions? |

2. Is the traffic being processed by the DUT correctly?

Table 7. Traffic behavior statistics

| Statistic Name | Behavior |
|---|---|
| Loss % Tx Frames Is the loss % experienced by flow groups the expected behavior? Rx Frames Compare the Loss % experienced by flow groups the expected behavior? | |
| Tx Frames | Is the loss % experienced by flow groups the expected behavior? |
| Rx Frames | Compare the Loss % with ingress and egress TOS precedence |
| Tx Frame Rate | values |
| Rx Frame Rate | |

3. How much Jitter (Delay Variation) is the DUT introducing to traffic as it processes the IP Precedence values in the header?

| Table 8. | Statistics highlighting the pass/fail result based on call flow execution |
|----------|---|
| Table 0. | oraristics myning the passian result based on can now execution |

| Statistic Name | Behavior |
|---|---|
| Average Delay Variation Min. Delay Variation | Are the successful loops and total loops values equal? |
| Max. Delay Variation | Have any failed loops, aborted loops, or warning loops been reported? |
| Small Error | |
| Big Error | |

Troubleshooting and Diagnostics

The following table summarizes some common issues that occur when running a layer 3 QoS test.

TEST CASE: LAYER 3 QUALITY OF SERVICE

Table 9. Common testing issues

| Issue | Solution |
|--|--|
| Can't ping to/from the DUT | Check the Protocol Interface tab and look for red exclamation marks (!). If found, there is likely an IP address or gateway mismatch. Ensure that the Discovered Neighbors tab has the correct information. |
| DUT starts to drop packets | |
| | Check the DUT configuration to verify that: The traffic transmit rate does not exceed the DUT egress port's capability. |
| | The DUT's configuration is set to drop packets when they cross a certain threshold. |
| The TOS precedence bits are not remarked | Verify that the policy on the DUT is setup to correctly identify and mark the packets. |

Test Variables

IxNetwork offers flexible and comprehensive coverage of layer 3 QoS test use cases. The values configured in the above test can be modified to test different layer 3 QoS test scenarios.

| Parameter Name | Options | | | | |
|--|--|--|--|--|--|
| Step 1. Number of Ports used | In this test we used two ports. However IxNetwork can be used to scale to large number of ports that can emulate real-life networks. | | | | |
| Step 2. Number of Endpoints | Traffic endpoints. | | | | |
| Step 3. TOS Precedence values | Any value from 000 (Routine) to 111 (network control). | | | | |
| Step 3. DSCP Values | DiffServ values for default, class-selector, assured and expedited forwarding can also be configured. | | | | |
| Step 4. Flow Group creation | Based upon IPv4 precedence value. However you can create flow groups based upon other criteria. | | | | |
| Step 5. Frame Size | This test used fixed frame size. IxNetwork also allows for other frame size mechanisms: Increment, random, IMIX, quad gaussian, or auto. | | | | |
| Step 6. Rate | 3% and 5% of line rate. These rates can be changed on the fly from the traffic grid. | | | | |
| Step 7. Flow Tracking | IPv4 precedence. There are many other flow tracking elements available depending on your requirements. | | | | |
| Step 7. Flow Tracking: Egress Tracking | IPv4 TOS precedence. There are many other egress tracking elements available for tracking. | | | | |

Table 10.Test tool parameters employed

Table 11.DUT test variables

| Parameter Name | Current Value/Behavior |
|----------------|------------------------|
| TOS Precedence | 7,4 and 0 |

| Action to perform when egress bandwidth is overloaded | Apply Layer 3 QoS policy configured to remark IP Precedence values from 4 to 5. IxNetwork can be used to verify that the DUT is performing the TOS header remarking correctly |
|--|---|
| Traffic Shaping | DUT can be configured to provide different traffic treatment to different QoS classes. IxNetwork statistics can be used to verify the traffic shaping results |

Conclusions

This test methodology demonstrated how to configure the parameters of a layer 3 QoS test, using practical examples and varying traffic loads. The DUT was configured to process TOS classes, resulting in different traffic behavior as the load was progressively increased.

Test Case: Impairment Testing For Layer 3 QoS Mechanisms

Overview

Real world networks suffer from network conditions such as drop, jitter and delay. To monitor and troubleshoot a network issue, routers and switches provide statistics to measure delay and drops. Service Providers and NEMs need to test that routers and switches are showing reliable statistics.

To test the capability of the router/switch under impaired conditions, an impairment generator is used. The statistics provided by the Impairment tool and the router/switch are compared to assess the reliability of the loss and delay measurements. This test case aims to introduce impairment tool setup.

Objective

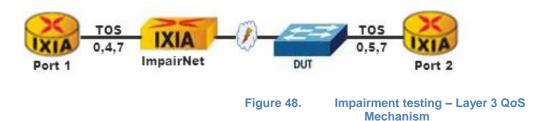

The objective of this test is to impair the traffic based on precedence value. The traffic will carry packets with precedence 0, 4 and 7. ImpairNet module is configured to selectively drop and delay the packets classified with precedence value.

The impairment module can be inserted in any link where it is needed. The steps used in this test case can be applied for Layer 3 VPN, multicast VPN and NG multicast VPN.

At the end of this test other test variables are discussed that provide more performance test cases.

Setup

The setup is similar to the setup of Test Case: Layer 3 Quality of ServiceLayer 3 QoS Mechanisms. The only difference is that an ImpairNet module is inserted between the Ixia test port (acting as source) and DUT.

Step by Step Instructions

These instructions will result in Delay, Jitter and Drop Impairment test for Layer 3 QoS topology shown in Figure 48. The steps below will guide you to build other Impairment test scenarios.

1. Follow the steps in the Test Case: Layer 3 Quality of Service to configure Layer 3 QoS Topology. Open the traffic item and clear the Precedence check box. This creates one traffic flow instead of three traffic flows. In the following steps, the traffic from the same flow will be impaired based on precedence value.

The traffic rate is configured as 2% in this test setup. If the traffic rate is different in your setup, then impairment statistics will vary.

2. Reserve two impairment ports in IxNetwork. The Impairment ports are added in the same way as other Ixia test ports with the exception that Impairment Ports are always selected as a port pair.

Optionally, rename the ImpairNet ports for easier reference throughout the IxNetwork application.

Figure 50.

Impairment Port Selection

 Ixia's IxNetwork Impairment GUI provides an easy to use one click option to create an impairment profile directly from the traffic flow group. Right click the desired flow group in L2-3 Flow Groups view and choose Create Impairment Profile from the menu.

Note: The view changes from L2-3 Flow Groups view to Network Impairment view after you click Create Impairment Profile.

4. The Network Impairment view has three tabs: Diagram, Profiles and Links. The Diagram tab is chosen by default. Select the **Profiles** tab to see the list of all the impairment profiles. This view has multiple tabs at bottom for different impairments.

| File Home Automa | tion | Results / R | eports | Views | Config | uration | |

Figure 52. Network Impairment view

Optionally, change the name of the impairment profile in the Profile Name grid for easy reference.

Note:

- The Network Impairment view has commands for creation, deletion, and raising or lowering the priority of the impairment profiles.
- The created impairment profile is enabled by default. Each profile has a checkbox to disable or enable it.
- Creating impairment profile directly from the traffic flow group has the advantage that all the L2-3 traffic classifiers are automatically added in the list of classifiers.
- Click the Classifier grid in the Network Impairment -> Profiles tab. The Packet Classifier dialogue opens.

| | - Packet | Classifier — | | # Matcher | s Used: 0/8 | |
|---|----------|--------------------------|--------|-------------------|-------------------|-------------------|
| | | | | | | |
| | a Add 💥 | Delete 📃 Edit | | | | |
| | Enabled | Pattern Name | Offset | Value | Mask | Field Size (bits) |
| 1 | | Ethernet.Destination M | 0 | 00:00:00:1A:A6:7B | FF:FF:FF:FF:FF | |
| | | Ethernet.Source MAC A | 6 | 00:00:00:1A:64:DA | FF:FF:FF:FF:FF:FF | |
| | | Ethernet.Ethernet-Type | 12 | 08 00 | FF FF | |
| | | IPv4.Protocol | 23 | 3D | FF | |
| | | IPv4.Source Address | 26 | 20.1.1.1 | 255.255.255.255 | |
| 1 | | IPv4.Destination Address | 30 | 20.1.1.2 | 255.255.255.255 | |

Figure 53. Open Traffic classifiers

6. Click the Add icon to add a new classifier pattern. Select Precedence in the Packet Templates Manager window.

Note: The selected field offset and size are shown at the bottom for reference. Optionally, remove all the unused classifier patterns.

| 🔯 Packet Templates Manager | | |
|---|---|--------|
| Packet Templates 🕀 💥 | IPv4 Packet | |
| 🗄 IPv4 Packet | Add/Remove Protocol Layers 🕀 🞇 🕼 🚸 | |
| IPv6 Packet IPv4_IPv6 Packet | Ethernet II Ethernet Header: 2 Destination MAC Address Source MAC Address Ethernet-Type IPv4 IP Header: 3 Version Header Length | |
| | IP Priority TOS Precedence | |
| 1 | Field (IPv4.Precedence) Offset (bytes): 15 | Cancel |
| | | |

Figure 54. Packet Templates Manager

7. Click **Ok** to close the **Packet Templates Manager** window. The field offset and size are automatically updated in the **Packet Classifier** dialogue.

The classifier pattern value has hexadecimal format and is aligned to an octet boundary. The unused bits in the value is ignored by using don't care bits in the mask.

In this test case, the traffic flow with precedence value **00** is impaired. The field size is 3 bits hence the other 5 bits should be ignored. The mask is 1 byte octet value and should be set to **E0**.

After the classifier is configured successfully, the pattern can be seen in the classifier grid.

| | | sifier | | | | | |

| | | | | | | | 1 |

- 8. Click **Add Profile** icon twice to create two profiles in Network Impairment Configuration ribbon. Optionally, name the profiles.
- Select the classifier added in step 9 and click the Copy Classifier icon. You can paste this classifier across multiple impairment profiles. Select the profiles created in step 10 individually and click Paste Classifier icon.
- 10. Edit the classifier to impair traffic for Precedence values 4 and 7. Only the value should be changed in the classifier.

| < > | | | | | | | | | |

Figure 59. Delay Impairment Configuration

14. Select the impairment profile and right click the **Delay Variation** grid. Select the **Enabled** check box and select the *Gaussian* as the delay variation. Enter *10 microseconds* as the value of Standard Variation as shown in Figure 60. Configure delay variation for the second and third profiles.

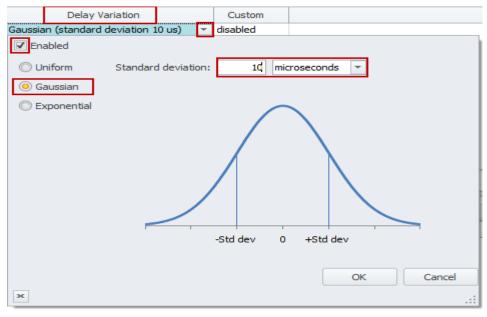

Figure 60. Jitter Impairment Configuration

15. To apply the impairment profile in the hardware, click on Apply Impairment icon in the configuration ribbon as shown in Figure 61. Only the enabled profiles are applied to the hardware. If applying impairment profile changes is successful, then the exclamation mark on the Apply Impairment icon will disappear.

TEST CASE: LAYER 3 QUALITY OF SERVICE

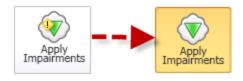

Figure 61. Apply Impairment Icon Change

Note: If the impairment profile contains configuration errors, then the exclamation mark will not disappear and an error notification pop-up will appear on the right hand side bottom corner of the IxNetwork GUI. For further troubleshooting, follow the instructions in the Troubleshooting Tips section.

16. After applying impairments, the impairment statistics also starts getting updated. Select Impairment Profiles and click on the Dropped tab at the bottom in the impairment statistics view as shown in Figure 62.

| | Impairment Statistics | Port CPU Statistics | s Impairment Link | Statistics | Impairment Profile | Statistics |
|-----|-----------------------------|---------------------|----------------------|--------------|--------------------|------------|
| | Stat Name | Dropped Frames | Dropped Frame Rate | Dropped Byte | s Dropped Bit Rate | |

| Þ | ▶ 1 P1 Impairment->P2 Impairme | | 73,680 |) 131,720 | 100,429 | 9,733 |
| | 2 | P2 Impairment->P1 Impairment | | | | |

Test Variables

Each of the following variables may be used in separate test cases to test the DUT. They use the test case detailed above as a baseline, and modify a few parameters in the same Network Impairment view. You can create various scalability tests to fully stress the DUT's capability as a PE router operating in presence of real world network impairments.

| Performance Variable | Description |
|---|--|
| Apply multiple profiles | You can create up to 32 bidirectional or 64 unidirectional impairment profiles per impairment port pair. |
| Use multiple classifiers | You can introduce multiple classifiers in a single impairment profile. Classifiers can also be copied and pasted across impairment profiles by using Copy Classifier and Paste Classifier commands in the Network Impairment Configuration tab. A maximum of 16 classifiers can be added for each link direction. |
| Apply impairments in both link directions | You can select to impair either one or both the links. See Figure 68. |
| Apply different drop rates | Apply drop rates from 0-100% in clusters, to a maximum of 65535 packets. |
| Apply different packet impairments | Apply, reorder, and duplicate BER impairments in addition to drop impairment. Reorder and duplicate impairments are present in the Packet Actions tab. |
| Increase Delay | Introduce delay to a maximum of 6s for every impairment profile on a 1G impairment module and to a maximum of 600 ms for a 10 G impairment module. |
| Apply different kind of delays | Introduce delay in us, ms or km. 1 km of WAN Link cause a delay of 5 us. |
| Apply different delay variations | You can apply uniform, exponential and customized delay variations. |

Results Analysis

The test verifies that drop and delay impairments can be introduced in the traffic stream based on precedence based traffic classifiers. The impairment profiles are independent of each other and each traffic flow is impaired independently. The drop and delay measurements can be used to verify the statistics report generated by DUT.

Troubleshooting Tips

| Issue | Troubleshooting Solution |
|--|---|
| Impairment profiles are enabled but impairment statistics are not updated. | Check that the Apply Impairments icon does not have any error mark. Check that the traffic is flowing and the drop rate is not configured to <i>100%</i> for all the profiles. |
| No traffic is flowing through the impairment links. | Disable all the impairment profiles except default profile. Make sure that the default profile is not set to <i>100%</i> drop. Apply Impairments, and check that Rx/Tx Frames statistics for the impairment link correspond to the traffic. Also, check that both the links for the impairment port pair are forwarding, that is, in the Links tab, clear the checkbox for Interrupt Forwarding . |
| An error window pops up in the right hand side bottom when Apply Impairments is clicked. | Check for impairment profile configuration error. Ensure that the impairments are applied with in the configuration limits. Check ImpairNet module specifications for the configuration limits. |
| Traffic is not getting impaired though the Apply Impairment icon is not showing any exclamation mark. | Check that the classifier value, mask and offset are set correctly. Also ensure that a profile with more generic classifier does not have a higher priority than that of the desired impairment profile. Also ensure that the Enabled checkbox is selected for the configured impairments. |

Conclusions

The test verifies that the ImpairNet is used as an effective and accurate impairment tool. The focus of this test was to impair traffic based on a particular packet field (precedence). Impairments can be generated for other fields to test the DUT's capability to generate accurate statistics report.

Test Case: Automating Layer 3 Quality of Service

Overview

The goal of this section is to show how to automate the above **Layer 3 Quality of Service** Test Case using IxNetwork Test Composer. Test Composer is part of the IxNetwork GUI Application.

This automation sequence will help the user understand how to:

1. Combine protocol configuration, traffic configuration, and automation sequence into one unified file.

This is accomplished through using the built-in Test Composer module to add automation to the L3 QoS configuration outlined in this test case. The benefit of using the IxNetwork Test Composer is that there is one IxNetwork file to be shared between teammates.

2. Reduce the setup and execution time for the DUT configuration.

This is accomplished through automatic capture of commands as they are entered into the CLI and automated playback on successive runs. The benefit of using the Capture/Replay module in Composer is the ability to create a DUT playback sequence without having the overhead of having to write a scripting language to send and expect the commands.

3. Configure the tester for traffic generation and control the duration of traffic.

This is accomplished by selecting Traffic events from the drop-down of command choices built-in to Composer. The benefit of using the built-in command wizard is that you can select the automation events you want from a GUI which shows you all of the events that are available.

4. Reduce the setup and execution of repeated traffic rate iterations.

This is accomplished by using a Composer variable to store the list of traffic rate iterations to be applied to a For-loop iterator. The benefit of using variables in an automation script is that you can make changes to the inputs in one place and it will change the execution of the entire sequence.

5. Collect traffic generator statistics per traffic rate iteration.

This is accomplished by using the StatQuery command to select statistics, in conjunction with the CSV Analyzer session to write them to a file. The benefit of using the StatQuery command is that you can select a subset of statistics from the GUI list of available statistics directly from the application.

6. Generate a single summary report using collected statistics in each iteration.

TEST CASE: AUTOMATING LAYER 3 QUALITY OF SERVICE

This is accomplished by using the Reporter session in Composer to read in the iteration CSVs and output them to HTML. The benefit of using the Reporter session is that you can customize the collection of statistics to meet the needs and format of your organization.

7. Specify pass/fail criteria to declare the overall success or failure of a test case execution.

This is accomplished by using the basic If expression builder to create a condition that checks for excessive frame loss. The benefit of having a clear pass/fail condition evaluated by the automation is that this yields a repeatable test case whose results can be quickly and easily compared against previous golden results.

In order to develop an end-to-end automation solution, the following sequence will help to organize the automation script into the key components needed to create a repeatable and portable test solution.

The complete automation script is obtained by opening the example IxNetwork Configuration for this methodology and clicking on the Test Composer icon to open the example script.

TEST CASE: AUTOMATING LAYER 3 QUALITY OF SERVICE

Sequence

- Open the IxNetwork GUI. Load the example configuration file: QoS-L3_v6.00_with_TC.ixncfg. This file can be found on the Black Book Web site. Go to <u>http://www.ixiacom.com/blackbook</u>. Find the 'Quality of Service Validation' Black Book and download the Templates.
- 2. Click **Test Composer** icon to open Test Composer which has the automation sequence.

TestComposer

8. Place the traffic events inside a **For** loop control flow statement and use it to select from a set of line rate values that can be stored in a variable called **LineRate** and passed as an argument to **Traffic Set Rate**. This will allow to iterate over multiple scenarios.

9. The dynamic nature of the IxNetwork traffic generation engine allows rates to be changed many times after traffic has been applied once to the port. Additional line rates can be added to the list of rates to scale the testing quickly.

Figure 72. Traffic Generator sequence changing line rate values in a loop

10. For more details on Ixia Traffic Generator Automation using Test Composer, please refer to the Getting Started Guide section of the Automation Blackbook entitled *Test Automation for IP Systems*.

A **Statistics StatQuery** command is used to select the traffic statistics from various detail views generated by IxNetwork.

- 11. Select the Traffic->Flow Filtering category.
- 12. In the Edit filter, make sure that Traffic Item is 1 and Rx Port is any of All.
- 13. In **Sorting Hiearchy**, select **All** to get both **Ingress Tracking** and **Egress Tracking** statistics.

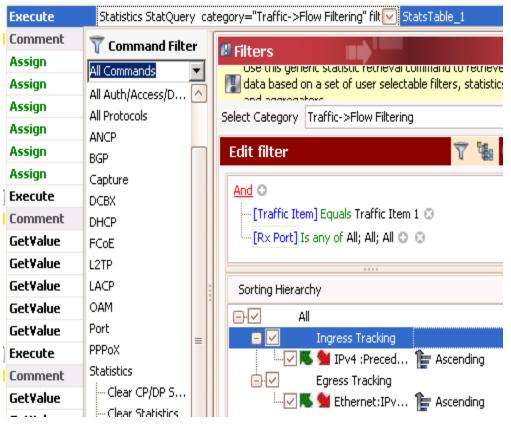

Figure 73. Using Statistics StatQuery to filter Traffic Ingress/Egress

14. In **Select Statistics**, select the *Loss %* statistic under the Traffic Statistics **Source Type**. When **Statistics StatQuery** is executed, the value of Loss % is automatically returned in a **Return Variable** called StatsTable_1.

Figure 74. Selecting Loss % statistic to be inluded in a Return Variable

The **GetValue** command is used to determine aggregate values across flows, and ports. such as Min, Max, and Average. This is used for determining the worst frame loss or longest latency for all traffic as an aggregate value in output CSV files.

In addition to the provided CSV reports in IxNetwork, the Session Manager includes a **CSVAnalyzer** session which can be used, for example, to read in automation input from a CSV file.

The **CSVAnalyze**r is also used to output Ixia Traffic Generator and DUT statistics to a CSV file using the **WriteBlock** command.

15. Use a **Basic If** Expression Builder to compare egress TOS variables against expected numerical values. Insert new rows and use the drop-downs in each column to select the variables and aggregation to be used in your expression.

Each row can be grouped into an AND expression where all sub-expressions must be true for the entire expression to be true.

| Conservation Configuration | | | | | | | | | |
